ABSTRACT. We study complexity of deep computations. We use topology of function spaces, specifically, the classification Rosenthal compacta, to identify new complexity classes. We use the language of model theory, specifically, the concept of the independence from Shelah's classification theory, to translate between topology and computation.

0. INTRODUCTION

In this paper we study limit behavior of real-valued computations as the value of certain parameters of the computation model tend towards infinity, or towards zero, or towards some other fixed value, e.g., the depth of a neural network tending to infinity, or the time interval between layers of the network tending toward zero. Recently, particular cases of this situation have attracted considerable attention in deep learning research (e.g., Neural Ordinary Differential Equations [CRBD], Physics-Informed Neural Networks [RPK19], deep equilibrium models [BKK], among others). In this paper, we combine ideas of topology, measure theory, and model theory to study these limit phenomena from a unified viewpoint.

Informed by model theory, to each computation in a given computation model, we associate a continuous real-valued function, called the *type* of the computation, that describes the logical properties of this computation with respect to the rest of the model. This allows us to view computations in any given computational model as elements of a space of real-valued functions, which is called the *space of types* of the model. The idea of embedding models of theories into their type spaces is central in model theory. The embedding of computations into spaces of types allows us to utilize the vast theory of topology of function spaces, known as C_p -theory, to obtain results about complexity of topological limits of computations. As we shall indicate next, recent classification results for spaces of functions provide an elegant and powerful machinery to classify computations according to their levels of “tameness” or “wildness”, with the former corresponding roughly to polynomial approximability and the latter to exponential approximability. The viewpoint of spaces of types, which we have borrowed from model theory, thus becomes a “Rosetta stone” that allows us to interconnect various classification programs: In topology, the classification of Rosenthal compacta pioneered by Todorčević [Tod99]; in logic, the classification of theories developed by Shelah [She90]; and in statistical learning, the notion PAC learning and VC dimension pioneered by Vapkins and Chervonenkis [VC74, VC71].

³⁶ In a previous paper [ADIW24], we introduced the concept of limits of computations, which we called *ultracomputations* (given they arise as ultrafilter limits of

³⁸ standard computations) and *deep computations* (following usage in machine learning [BKK]). There is a technical difference between both designations, but in this
³⁹ paper, to simplify the nomenclature, we will ignore the difference and use only the
⁴⁰ term “deep computation”.

⁴¹ In [ADIW24], we proved a new “tame vs wild” (i.e., polynomial vs exponential)
⁴² dichotomy for complexity of deep computations by invoking a classical result of
⁴³ Grothendieck from late 50s [Gro52]. Under our model-theoretic Rosetta stone,
⁴⁴ polynomial approximability in the sense of computation becomes identified with the
⁴⁵ notion of continuous extendability in the sense of topology, and with the notions of
⁴⁶ *stability* and *type definability* in the sense of model theory.
⁴⁷

⁴⁸ In this paper, we follow a more general approach, i.e., we view deep computations
⁴⁹ as pointwise limits of continuous functions. In topology functions that arise as the
⁵⁰ pointwise limit of a sequence of continuous are called *functions of the first Baire*
⁵¹ class, or *Baire class 1* functions, or *Baire-1* for short; Baire class 1 form a step above
⁵² simple continuity in the hierarchy of functions studied in real analysis (Baire class
⁵³ 0 functions being continuous functions). Intuitively, Baire-1 functions represent
⁵⁴ functions with “controlled” discontinuities, so they are crucial in topology and set
⁵⁵ theory.

⁵⁶ We prove a new “tame vs wild” Ramsey-theoretic dichotomy for complexity of
⁵⁷ general deep computations by invoking a famous paper by Bourgain, Fremlin and
⁵⁸ Talagrand from the late 70s [BFT78], and a new trichotomy for the class of “tame”
⁵⁹ deep computations by invoking an equally celebrated result of Todorčević, from the
⁶⁰ late 90s, for functions of the first Baire class [Tod99].

⁶¹ Todorčević’s trichotomy regards *Rosenthal compacta*; these are special classes of
⁶² topological spaces, defined as compact spaces that can be embedded (homeomor-
⁶³ phically identified as a subset) within the space of Baire class 1 functions on some
⁶⁴ Polish (separable, complete metric) space, under the pointwise convergence topol-
⁶⁵ ogy. Rosenthal compacta exhibit “topological tameness,” meaning that they behave
⁶⁶ in relatively controlled ways, and since the late 70’s, they have played a crucial role
⁶⁷ for understanding complexity of structures of functional analysis, especially, Banach
⁶⁸ spaces. Todorčević’s trichotomy has been utilized to settle longstanding problems
⁶⁹ in topological dynamics and topological entropy [GM22].

⁷⁰ Through our Rosetta stone, Rosenthal compacta in topology correspond to the
⁷¹ important concept of “No Independence Property” (known as “NIP”) in model
⁷² theory, identified by Shelah [She71, She90], and to the concept of Probably Ap-
⁷³ proximately Correct learning (known as “PAC learnability”) in statistical learning
⁷⁴ theory identified by Valiant [Val84].

⁷⁵ Going beyond Todorčević’s trichotomy, we invoke a more recent heptachotomy
⁷⁶ for Rosenthal compacta obtained by Argyros, Dodos and Kanellopoulos [ADK08].
⁷⁷ Argyros, Dodos and Kanellopoulos identified seven fundamental “prototypes” of
⁷⁸ separable Rosenthal compacta, and proved that any non-metrizable separable Rosen-
⁷⁹ thal compactum must contain a “canonical” embedding of one of these prototypes.
⁸⁰ They showed that if a separable Rosenthal compactum is not hereditarily separable,
⁸¹ it must contain an uncountable discrete subspace of the size of the continuum.

⁸² We believe that the results presented in this paper show practitioners of com-
⁸³ putation, or topology, or descriptive set theory, or model theory, how classification
⁸⁴ invariants used in their field translate into classification invariants of other fields.
⁸⁵ However, in the interest of accessibility, we do not assume previous familiarity with

⁸⁶ high-level topology or model theory, or computing. The only technical prerequisite
⁸⁷ of the paper is undergraduate-level topology and measure theory. The necessary
⁸⁸ topological background beyond undergraduate topology is covered in section 1.

Throughout the paper, we focus on classical computation; however, by refining the model-theoretic tools, the results presented here can be extended to quantum computation and open quantum systems. This extension will be addressed in a forthcoming paper.

In this section we give preliminaries from general topology and function space theory. We include some of the proofs for completeness, but the reader familiar with these topics may skip them.

Recall that a subset of a topological space is F_σ if it is a countable union of closed sets, and G_δ if it is a countable intersection of closed sets. Note that in a metrizable space, every open set is F_σ ; equivalently, every closed set is G_δ .

A *Polish space* is a separable and completely metrizable topological space. The most important examples are the reals \mathbb{R} , the Cantor space $2^{\mathbb{N}}$ (the set of all infinite binary sequences, endowed with the product topology), and the Baire space $\mathbb{N}^{\mathbb{N}}$ (the set of all infinite sequences of naturals, also with the product topology). Countable

products of Polish spaces are Polish; this includes spaces like $\mathbb{R}^{\mathbb{N}}$, the space of sequences of real numbers.

In this paper, we shall discuss subspaces, and so there is a pertinent subtlety of the definitions worth mentioning: *completely metrizable space* is not the same as *complete metric space*; for an illustrative example, the interval $(0, 1)$ with the metric inherited from the reals is complete, but it is Polish since that is homeomorphic to the real line. Being Polish is a topological property.

The following result is a cornerstone of descriptive set theory, closely tied to the work of Waclaw Sierpiński and Kazimierz Kuratowski, with proofs often built upon their foundations and formalized later, notably, involving Stefan Mazurkiewicz's work on complete metric spaces.

Fact 1.1. *A subset A of a Polish space X is itself Polish in the subspace topology if and only if it is a G_δ set. In particular, closed subsets and open subsets of Polish spaces are also Polish spaces.*

Given two topological spaces X and Y we denote by $C_p(X, Y)$ the set of all continuous functions $f : X \rightarrow Y$ endowed with the topology of pointwise convergence. When $Y = \mathbb{R}$, we denote this collection simply as $C_p(X)$. A natural question is, how do topological properties of X translate into $C_p(X)$ and vice versa? These questions, and in general the study of these spaces, are the concern of C_p -theory, an active field of research in general topology which was pioneered by A. V. Arhangel'skiĭ and his students in the 1970's and 1980's. This field has found many applications in model theory and functional analysis. Recent surveys on the topics include [HT23] and [Tka11].

A *Baire class 1* function between topological spaces is a function that can be expressed as the pointwise limit of a sequence of continuous functions. If X and Y are topological spaces, the Baire class 1 functions $f : X \rightarrow Y$ endowed with the topology of pointwise convergence is denoted $B_1(X, Y)$. As above, in the special case $Y = \mathbb{R}$ we denote $B_1(X, Y)$ as $B_1(X)$. Clearly, $C_p(X, Y) \subseteq B_1(X, Y)$. The Baire hierarchy of functions was introduced by René-Louis Baire in his 1899 doctoral thesis, *Sur les fonctions de variables réelles*. His work moved away from the 19th-century preoccupation with “pathological” functions toward a constructive classification based on pointwise limits.

A topological space X is *perfectly normal* if it is normal and every closed subset of X is a G_δ (equivalently, every open subset of X is a G_δ). Note that every metrizable space is perfectly normal.

The following fact was established by Baire in thesis. A proof can be found in Section 10 of [Tod97].

Fact 1.2 (Baire). *If X is perfectly normal, then the following conditions are equivalent for a function $f : X \rightarrow \mathbb{R}$:*

- f is a Baire class 1 function, that is, $f \in B_1(X)$.
- $f^{-1}[U]$ is an F_σ subset of X whenever $U \subseteq \mathbb{R}$ is open.
- f is a pointwise limit of continuous functions.
- For every closed $F \subseteq X$, the restriction $f|_F$ has a point of continuity.

Moreover, if X is Polish and $f \notin B_1(X)$, then there exists countable $D_0, D_1 \subseteq X$ and reals $a < b$ such that

$$D_0 \subseteq f^{-1}(-\infty, a], \quad D_1 \subseteq f^{-1}[b, \infty), \quad \overline{D_0} = \overline{D_1}.$$

174 A subset L of a topological space X is *relatively compact* in X if the closure
 175 of L in X is compact. Relatively compact subsets of $B_1(X)$ (for X Polish) have
 176 been objects of interest for researchers in Analysis and Topological Dynamics. We
 177 begin with the following well-known result. Recall that a set $A \subseteq \mathbb{R}^X$ of real-
 178 valued functions is *pointwise bounded* if for every $x \in X$ there is $M_x > 0$ such that
 179 $|f(x)| < M_x$ for all $f \in A$. We include a proof for the reader's convenience:

180 **Lemma 1.3.** *Let X be a Polish space and $A \subseteq B_1(X)$ be pointwise bounded. The
 181 following are equivalent:*

- 182 (i) A is relatively compact in $B_1(X)$.
- 183 (ii) A is relatively countably compact in $B_1(X)$, i.e., every countable subset of
 184 A has an accumulation point in $B_1(X)$.
- 185 (iii) $\overline{A} \subseteq B_1(X)$, where \overline{A} denotes the closure in \mathbb{R}^X .

186 *Proof.* Since A is pointwise bounded, for each $x \in X$, fix $M_x > 0$ such that $|f(x)| \leq$
 187 M_x for every $f \in A$.

188 (i) \Rightarrow (ii) holds in general.

189 (ii) \Rightarrow (iii) Assume that A is relatively countably compact in $B_1(X)$ and that
 190 $f \in \overline{A} \setminus B_1(X)$. By Fact 1.2, there are countable $D_0, D_1 \subseteq X$ with $\overline{D_0} = \overline{D_1}$, and
 191 $a < b$ such that $D_0 \subseteq f^{-1}(-\infty, a]$ and $D_1 \subseteq f^{-1}[b, \infty)$. We claim that there is a
 192 sequence $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ such that $\lim_{n \rightarrow \infty} f_n(x) = f(x)$ for all $x \in D_0 \cup D_1$. Indeed,
 193 use the countability to enumerate $D_0 \cup D_1$ as $\{x_n\}_{n \in \mathbb{N}}$. Then for each positive n
 194 find $f_n \in A$ with $|f_n(x_i) - f(x_i)| < \frac{1}{n}$ for all $i \leq n$. The claim follows.

195 By relative countable compactness of A , there is an accumulation point $g \in$
 196 $B_1(X)$ of $\{f_n\}_{n \in \mathbb{N}}$. It is straightforward to show that since f and g agree on
 197 $D_0 \cup D_1$, g does not have a point of continuity on the closed set $\overline{D_0} = \overline{D_1}$, which
 198 contradicts Fact 1.2.

199 (iii) \Rightarrow (i) Suppose that $\overline{A} \subseteq B_1(X)$. Then $\overline{A} \cap B_1(X) = \overline{A}$ is a closed subset of
 200 $\prod_{x \in X} [-M_x, M_x]$; Tychonoff's theorem states that the product of compact spaces
 201 is always compact, and since closed subsets of compact spaces are compact, \overline{A} must
 202 be compact, as desired. \square

203 **1.1. From Rosenthal's dichotomy to the Bourgain-Fremlin-Talagrand di-
 204 chotomy to Shelah's NIP.** In metrizable spaces, points of closure of some subset
 205 can always be approximated by points inside the set, via a convergent sequence.
 206 For more complicated spaces, such as $C_p(X)$, this fails in remarkable ways. To
 207 see an example, consider the Cantor space $X = 2^\mathbb{N}$, and for each $n \in \mathbb{N}$ define
 208 $p_n : X \rightarrow \{0, 1\}$ by $p_n(x) = x(n)$ for each $x \in X$. Then p_n is continuous for each
 209 n , but one can show (see Chapter 1.1 of [Tod97] for details) that the only continu-
 210 ous functions in the closure of $\{p_n\}_{n \in \mathbb{N}}$ are the functions p_n themselves; moreover,
 211 none of the subsequences of $\{p_n\}_{n \in \mathbb{N}}$ converge. In some sense, this example is the
 212 worst possible scenario for convergence. The topological space obtained from this
 213 closure is well-known: it is the *Stone-Čech compactification* of the discrete space of
 214 natural numbers, or $\beta\mathbb{N}$ for short, and it is an important object of study in general
 215 topology.

216 The following theorem, established by Haskell Rosenthal in 1974, is fundamental
 217 in functional analysis, and describes a sharp division in the behavior of sequences
 218 within a Banach space:

219 **Theorem 1.4** (Rosenthal's Dichotomy, [Ros74]). *If X is Polish and $\{f_n\} \subseteq C_p(X)$
220 is pointwise bounded, then either $\{f_n\}_{n \in \mathbb{N}}$ contains a convergent subsequence or a
221 subsequence whose closure (in \mathbb{R}^X) is homeomorphic to $\beta\mathbb{N}$.*

222 In other words, a pointwise bounded set of continuous functions either contains
223 a convergent subsequence, or a subsequence whose closure is essentially the same as
224 the example mentioned in the previous paragraphs (the “wildest” possible scenario).
225 Note that in the preceding example, the functions are trivially pointwise bounded
226 in \mathbb{R}^X as the functions can only take values 0 and 1.

227 The genesis of Theorem 1.4 was Rosenthal’s ℓ_1 theorem, which states that the
228 only reason why Banach space can fail to have an isomorphic copy of ℓ_1 (the space
229 of absolutely summable sequences) is the presence of a bounded sequence with no
230 weakly Cauchy subsequence. The theorem is famous for connecting diverse areas
231 of mathematics, namely, Banach space geometry, Ramsey theory, set theory, and
232 topology of function spaces.

233 As we move from $C_p(X)$ to the larger space $B_1(X)$, we find a similar dichotomy.
234 Either every point of closure of the set of functions will be a Baire class 1 function,
235 or there is a sequence inside the set that behaves in the wildest possible way. The
236 theorem is usually not phrased as a dichotomy but rather as an equivalence:

237 **Theorem 1.5** (The BFT Dichotomy. Bourgain-Fremlin-Talagrand, [BFT78, The-
238 oreom 4G]). *Let X be a Polish space and $A \subseteq C_p(X)$ be pointwise bounded. The
239 following are equivalent:*

- 240 (i) *A is relatively compact in $B_1(X)$, i.e., $\overline{A} \subseteq B_1(X)$.*
- 240 (ii) *For every $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ and every $a < b$ there is $I \subseteq \mathbb{N}$ such that*

$$\bigcap_{n \in I} f_n^{-1}(-\infty, a] \cap \bigcap_{n \notin I} f_n^{-1}[b, \infty) = \emptyset.$$

241 **Definition 1.6.** We shall say that a set $A \subseteq \mathbb{R}^X$ satisfies the *Independence Prop-
242 erty*, or IP for short, if it satisfies the following condition: There exists every
243 $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ and $a < b$ such that for every pair of disjoint sets $E, F \subseteq \mathbb{N}$, we
244 have

$$\bigcap_{n \in E} f_n^{-1}(-\infty, a] \cap \bigcap_{n \in F} f_n^{-1}[b, \infty) \neq \emptyset.$$

245 If A satisfies the negation of this condition, we will say that A *satisfies NIP*, or
246 that has the NIP.

Remark 1.7. Note that if X is compact and $A \subseteq C_p(X)$, then A satisfies the NIP
if and only if for every $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ and for every $a < b$ there is $I \subseteq \mathbb{N}$ such that

$$\bigcap_{n \in I} f_n^{-1}(-\infty, a] \cap \bigcap_{n \notin I} f_n^{-1}[b, \infty) = \emptyset.$$

247 To summarize, the particular case of Theorem 1.8 for X compact can be stated
248 in the following way:

249 **Theorem 1.8.** *Let X be a compact Polish space. Then, for every pointwise bounded
250 $A \subseteq C_p(X)$, one and exactly one of the following two conditions must hold:*

- 251 (i) $\overline{A} \subseteq B_1(X)$.
- 252 (ii) A has NIP.

253 The Independence Property was first isolated by Saharon Shelah in model theory
 254 as a dividing line between theories whose models are “tame” (corresponding to
 255 NIP) theories of models are “wild” (corresponding to IP). See [She71, Definition
 256 4.1],[She90]. We will discuss this dividing line in more detail in the next section.

257 **1.2. NIP as universal dividing line between polynomial and exponential**
 258 **complexity.** The particular case of the BFT Dichotomy (Theorem 1.8) when A
 259 consists of $\{0, 1\}$ -valued (i.e., {Yes, No}-valued) strings was discovered indepen-
 260 dently, around 1971-1972 in many foundational contexts related to polynomial
 261 (“tame”) vs exponential (“wild”) complexity: In model theory, by Saharon She-
 262 lah [She71],[She90],in combinatorics, by Norbert Sauer [Sau72], and Shelah [She72,
 263 She90], and in statistical learning, by Vladimir Vapnik and Alexey Chervonenkis [VC71,
 264 VC74].

265 **In model theory:** Shelah’s classification theory is a foundational program
 266 in mathematical logic devised to categorize first-order theories based on
 267 the complexity and structure of their models. A theory T is considered
 268 classifiable in Shelah’s sense if the number of non-isomorphic models of T
 269 of a given cardinality can be described by a bounded number of numerical
 270 invariants. In contrast, a theory T is unclassifiable if the number of models
 271 of T of a given cardinality is the maximum possible number. The number
 272 of models of T is directly impacted by the number of “types” over of pa-
 273 rameters in models of T ; a controlled number of types is a characteristic of
 274 a classifiable theory.

275 In Shelah’s classification program [She90], theories without the indepen-
 276 dence property (called NIP theories, or dependent theories) have a well-
 277 behaved, “tame” structure; the number of types over a set of parameters
 278 of size κ of such a theory is of polynomially or similar “slow” growth on κ .
 279 In contrast, Theories with the Independence Property (called IP theories)
 280 are considered “intractable” or “wild”. A theory with the Independence
 281 Property produces the maximum possible number of types over a set of
 282 parameters; for a set of parameters of cardinality κ , the theory will have
 283 2^{2^κ} -many distinct types.

284 **In combinatorics:** Sauer [Sau72] and Shelah [She72] proved the following:
 285 If $\mathcal{F} = \{S_0, S_1, \dots\}$ is a family of subsets of some infinite set S , then
 286 either for every $n \in \mathbb{N}$, there is either a set $A \subseteq S$ with $|A| = n$ such that
 287 $|\{S_i \cap A\} : i \in \mathbb{N}\}| = 2^n$ (yielding exponential complexity), or there exists
 288 $N \in \mathbb{N}$ such that for every $A \subseteq S$ with $|A| \geq N$, one has

$$|\{S_i \cap A\} : i \in \mathbb{N}\| \leq \sum_{i=0}^{N-1} \binom{|A|}{i} \approx O(|A|^N)$$

289 (yielding polynomial complexity). This answered a question of Erdős.

290 **In machine learning:** Readers familiar with statistical learning may rec-
 291 ognize the Sauer-Shelah lemma as the dichotomy discovered and proved
 292 slightly earlier (1971) by Vapnik and Chervonenkis [VC71, VC74] to ad-
 293 dress the problem of uniform convergence in statistics. The least integer
 294 N given by the preceding paragraph, when it exists, is called the *VC-*
 295 *dimension* of \mathcal{F} . This is a core concept in machine learning. If such an
 296 integer N does not exist, we say that the VC-dimension of \mathcal{F} is infinite. The

297 lemma provides upper bounds on the number of data points (sample size m)
 298 needed to learn a concept class with VC dimension $d \in \mathbb{N}$ by showing this
 299 number grows polynomially with m and d (namely, $\sum_{i=0}^d \binom{m}{i} \approx O(m^d)$),
 300 not exponentially. The Fundamental Theorem of Statistical Learning states
 301 that a hypothesis class is PAC-learnable (PAC stands for “Probably Ap-
 302 proximately Correct”) if and only if its VC dimension is finite.

303 **1.3. Rosenthal compacta.** The comprehensiveness of Theorem 1.8, attested by
 304 the examples outlined in the preceding section, led to the following definition (iso-
 305 lated by Gilles Godefroy [God80]):

306 **Definition 1.9.** A Rosenthal compactum is a compact Hausdorff topological space
 307 K that can be topologically embedded as a compact subset into the space of all
 308 functions of the first Baire class on some Polish space X , equipped with the topology
 309 of pointwise convergence.

310 Rosenthal compacta are characterized by significant topological and dynamical
 311 tameness properties. They play an important role in functional analysis, measure
 312 theory, dynamical systems, descriptive set theory, and model theory. In this paper,
 313 we introduce their applicability in deep computation. For this, we shall first focus
 314 on countable languages, which is the theme of the next subsection.

315 **1.4. The special case $B_1(X, \mathbb{R}^{\mathcal{P}}$ with \mathcal{P} countable.** Our goal now is to charac-
 316 terize relatively compact subsets of $B_1(X, Y)$ for the particular case when $Y = \mathbb{R}^{\mathcal{P}}$
 317 with \mathcal{P} countable. Given $P \in \mathcal{P}$ we denote the projection map onto the P -coordinate
 318 by $\pi_P : \mathbb{R}^{\mathcal{P}} \rightarrow \mathbb{R}$. From a high-level topological interpretation, the next lemma
 319 states that, in this context, the spaces \mathbb{R} and $\mathbb{R}^{\mathcal{P}}$ are really not that different,
 320 and that if we understand the Baire class 1 functions of one space, then we also
 321 understand the functions of both.

322 **Lemma 1.10.** Let X be a Polish space and \mathcal{P} be a countable set. Then, $f \in$
 323 $B_1(X, \mathbb{R}^{\mathcal{P}})$ if and only if $\pi_P \circ f \in B_1(X)$ for all $P \in \mathcal{P}$.

Proof. Only one implication needs a proof. Suppose that $\pi_P \circ f \in B_1(X)$ for all
 $P \in \mathcal{P}$. Let V be a basic open subset of $\mathbb{R}^{\mathcal{P}}$. That is, there exists a finite $\mathcal{P}' \subseteq \mathcal{P}$
such that $V = \bigcap_{P \in \mathcal{P}'} \pi_P^{-1}[U_P]$ where U_P is open in \mathbb{R} . Then,

$$f^{-1}[V] = \bigcap_{P \in \mathcal{P}'} (\pi_P \circ f)^{-1}[U_P]$$

324 is an F_σ set. Since \mathcal{P} is countable, $\mathbb{R}^{\mathcal{P}}$ is second countable so every open set U in
 325 $\mathbb{R}^{\mathcal{P}}$ is a countable union of basic open sets. Hence, $f^{-1}[U]$ is F_σ . \square

326 Below we consider \mathcal{P} with the discrete topology. For each $f : X \rightarrow \mathbb{R}^{\mathcal{P}}$ denote
 327 $\hat{f}(P, x) := \pi_P \circ f(x)$ for all $(P, x) \in \mathcal{P} \times X$. Similarly, for each $g : \mathcal{P} \times X \rightarrow \mathbb{R}$ denote
 328 $\check{g}(x)(P) := g(P, x)$. Given $A \subseteq (\mathbb{R}^{\mathcal{P}})^X$, we denote \hat{A} as the set of all \hat{f} such that
 329 $f \in A$. Note that the map $(\mathbb{R}^{\mathcal{P}})^X \rightarrow \mathbb{R}^{\mathcal{P} \times X}$ given by $f \mapsto \hat{f}$ is a homeomorphism
 330 and its inverse is given by $g \mapsto \check{g}$.

331 **Lemma 1.11.** Let X be a Polish space and \mathcal{P} be countable. Then, $f \in B_1(X, \mathbb{R}^{\mathcal{P}})$
 332 if and only if $\hat{f} \in B_1(\mathcal{P} \times X)$.

Proof. (\Rightarrow) By Lemma 1.10, given an open set of reals U , we have $f^{-1}[\pi_P^{-1}[U]]$ is F_σ for every $P \in \mathcal{P}$. Given that \mathcal{P} is a discrete countable space, we observe that

$$\hat{f}^{-1}[U] = \bigcup_{P \in \mathcal{P}} (\{P\} \times f^{-1}[\pi_P^{-1}[U]])$$

is an F_σ as well.

(\Leftarrow) By lemma 1.10 it suffices to show that $\pi_P \circ f \in B_1(X)$ for all $P \in \mathcal{P}$. Fix an open $U \subseteq \mathbb{R}$. Write $\hat{f}^{-1}[U] = \bigcup_{n \in \mathbb{N}} F_n$ where F_n is closed in $\mathcal{P} \times X$. Then,

$$(\pi_P \circ f)^{-1}[U] = \bigcup_{n \in \mathbb{N}} \{x \in X : (P, x) \in F_n\}$$

which is F_σ . \square

Given $A \subseteq Y^X$ and $K \subseteq X$ we write $A|_K := \{f|_K : f \in A\}$, i.e., the set of all restrictions of functions in A to K . The following Theorem is a slightly more general version of Theorem 1.8.

Theorem 1.12. *Assume that \mathcal{P} is countable, X is a Polish space, and $A \subseteq C_p(X, \mathbb{R}^\mathcal{P})$ is such that $\pi_P \circ A$ is pointwise bounded for all $P \in \mathcal{P}$. The following are equivalent for every compact $K \subseteq X$:*

- (1) $\overline{A|_K} \subseteq B_1(K, \mathbb{R}^\mathcal{P})$.
- (2) $\pi_P \circ A|_K$ satisfies the NIP for every $P \in \mathcal{P}$.

Proof. (1) \Rightarrow (2). Let $P \in \mathcal{P}$. Fix $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ and $a < b$. By (1), we have $\overline{A|_K} \subseteq B_1(K, \mathbb{R}^\mathcal{P})$. Applying the homeomorphism $f \mapsto \hat{f}$ and using lemma 1.11 we get $\hat{A}|_{\mathcal{P} \times K} \subseteq B_1(\mathcal{P} \times K)$. By Theorem 1.8, there is $I \subseteq \mathbb{N}$ such that

$$(\mathcal{P} \times K) \cap \bigcap_{n \in I} \hat{f}_n^{-1}(-\infty, a] \cap \bigcap_{n \notin I} \hat{f}_n^{-1}[b, \infty) = \emptyset$$

Hence,

$$K \cap \bigcap_{n \in I} (\pi_P \circ f_n)^{-1}(-\infty, a] \cap \bigcap_{n \notin I} (\pi_P \circ f_n)^{-1}[b, \infty) = \emptyset$$

By the compactness of K , there are finite $E \subseteq I$ and $F \subseteq \mathbb{N} \setminus I$ such that

$$K \cap \bigcap_{n \in E} (\pi_P \circ f_n)^{-1}(-\infty, a] \cap \bigcap_{n \in F} (\pi_P \circ f_n)^{-1}[b, \infty) = \emptyset$$

Thus, $\pi_P \circ A|_L$ satisfies the NIP.

(2) \Rightarrow (1) Fix $f \in \overline{A|_K}$. By lemma 1.10 it suffices to show that $\pi_P \circ f \in B_1(K)$ for all $P \in \mathcal{P}$. By (2), $\pi_P \circ A|_K$ satisfies the NIP. Hence, by Theorem 1.8 we have $\pi_P \circ A|_K \subseteq B_1(K)$. But then $\pi_P \circ f \in \overline{\pi_P \circ A|_K} \subseteq B_1(K)$. \square

Lastly, a simple but useful lemma that helps understand when we restrict a set of functions to a specific subspace of the domain space, we may always assume that the subspace is closed, as replacing the subspace by its closure has no effect on NIP.

Lemma 1.13. *Assume that X is Hausdorff and that $A \subseteq C_p(X)$. The following are equivalent for every $L \subseteq X$:*

- (i) A_L satisfies the NIP.
- (ii) $A|_{\overline{L}}$ satisfies the NIP.

Proof. It suffices to show that (i) \Rightarrow (ii). Suppose that (ii) does not hold, i.e., that there are $\{f_n\}_{n \in \mathbb{N}} \subseteq A$ and $a < b$ such that for all finite disjoint $E, F \subseteq \mathbb{N}$:

$$\bar{L} \cap \bigcap_{n \in E} f_n^{-1}(-\infty, a] \cap \bigcap_{n \in F} f_n^{-1}[b, \infty) \neq \emptyset.$$

Pick $a' < b'$ such that $a < a' < b' < b$. Then, for any finite disjoint $E, F \subseteq \mathbb{N}$ we can choose

$$x \in \bar{L} \cap \bigcap_{n \in E} f_n^{-1}(-\infty, a') \cap \bigcap_{n \in F} f_n^{-1}(b', \infty)$$

By definition of closure:

$$L \cap \bigcap_{n \in E} f_n^{-1}(-\infty, a'] \cap \bigcap_{n \in F} f_n^{-1}[b', \infty) \neq \emptyset.$$

354 This contradicts (i). □

355 2. COMPOSITIONAL COMPUTATION STRUCTURES.

356 In this section, we connect function spaces with floating point computation. We
357 start by summarizing some basic concepts from [ADIW24].

358 A *computation states structure* is a pair (L, \mathcal{P}) , where L is a set whose elements we
359 call *states* and \mathcal{P} is a collection of real-valued functions on L that we call *predicates*.
360 For a state $v \in L$, *type* of v is defined as the indexed family

$$\text{tp}(v) = (P(v))_{P \in \mathcal{P}} \in \mathbb{R}^{\mathcal{P}}.$$

361 For each $P \in \mathcal{P}$, we call real value $P(v)$ the P -th *feature* of v . A *transition* of a
362 computation states structure (L, \mathcal{P}) is a map $f : L \rightarrow L$.

363 Intuitively, L is the set of states of a computation, and the predicates $P \in \mathcal{P}$
364 are primitives that are given and accepted as computational. We think of each
365 state $v \in L$ as being uniquely characterized by its type $\text{tp}(v)$. Thus, in practice,
366 we identify L with a subset of $\mathbb{R}^{\mathcal{P}}$. A typical case will be when $L = \mathbb{R}^{\mathbb{N}}$ or $L = \mathbb{R}^n$
367 for some positive integer n and there is a predicate $P_i(v) = v_i$ for each of the
368 coordinates v_i of v . We regard the space of types as a topological space, endowed
369 with the topology of pointwise convergence inherited from $\mathbb{R}^{\mathcal{P}}$. In particular, for
370 each $P \in \mathcal{P}$, the projection map $v \mapsto P(v)$ is continuous.

371 **Definition 2.1.** Given a computation states structure (L, \mathcal{P}) , any element of $\mathbb{R}^{\mathcal{P}}$
372 in the image of L under the map $v \mapsto \text{tp}(v)$ will be called a *realized type*. The
373 topological closure of the set of realized types in $\mathbb{R}^{\mathcal{P}}$ (endowed with the point-
374 wise convergence topology) will be called the *space of types* of (L, \mathcal{P}) , denoted \mathcal{L} .
375 Elements of $\mathcal{L} \setminus L$ will be called *unrealized types*.

376 In traditional model theory, the space of types of a structure is viewed as a sort
377 of compactification of the structure, and the compactness of type spaces plays a
378 central role. However, the space \mathcal{L} defined above is not necessarily compact. To
379 bypass this obstacle, we follow the idea introduced in [ADIW24] of covering \mathcal{L} by
380 “thin” compact subspaces that we call *shards*. The formal definition of shard is
381 next.

382 **Definition 2.2.** A *sizer* is a tuple $r_{\bullet} = (r_P)_{P \in \mathcal{P}}$ of positive real numbers indexed
383 by \mathcal{P} . Given a sizer r_{\bullet} , we define the r_{\bullet} -*shard* as:

$$L[r_{\bullet}] = L \cap \prod_{P \in \mathcal{P}} [-r_P, r_P].$$

384 For a sizer r_\bullet , the r_\bullet -*type shard* is defined as $\mathcal{L}[r_\bullet] = \overline{L[r_\bullet]}$. We define \mathcal{L}_{sh} , as
 385 the union of all type-shards.

386 **Definition 2.3.** A *Compositional Computation Structure* (CCS) is a triple (L, \mathcal{P}, Γ) ,
 387 where

- 388 • (L, \mathcal{P}) is a computation states structure, and
 389 • $\Gamma \subseteq L^L$ is a semigroup under composition.

390 The elements of the semigroup Γ are called the *computations* of the structure
 391 (L, \mathcal{P}, Γ) .

392 If $\Delta \subseteq \Gamma$, we say that $\Delta \subseteq \Gamma$ is *R-confined* if $\gamma|_{L[r_\bullet]} : L[r_\bullet] \rightarrow L[r_\bullet]$ for every
 393 $r_\bullet \in R$ and $\gamma \in \Delta$. Elements in $\overline{\Delta} \subseteq \mathcal{L}_{\text{sh}}$ are called (real-valued) *deep computations*
 394 or *ultracomputations*.

395 A tenet of our approach is that a map $f : L \rightarrow \mathcal{L}$ is to be considered “effectively
 396 computable” if, for each $Q \in \mathcal{P}$, the output feature $Q \circ f : L \rightarrow \mathbb{R}$ is a *definable*
 397 predicate in the following sense:

398 Given any arbitrary $\varepsilon > 0$ and any $K \subseteq L$ wherein every input feature $P(v)$
 399 remains bounded in magnitude there is an ε -approximating continuous “algebraic”
 400 operator $\varphi(P_1, \dots, P_n)$ of finitely many input predicates $P_1, \dots, P_n \in \mathcal{P}$, such that
 401 the following holds: for all $v \in K$, the output feature $Q(f(v))$ is ε -approximated
 402 by $\varphi(P_1(v), \dots, P_n(v))$. By “algebraic”, we mean that, aside from the primitives
 403 P_1, \dots, P_n , the approximating operator $\varphi(P_1, \dots, P_n)$ uses only the algebra operations
 404 of $\mathbb{R}^{\mathcal{P}}$, i.e., vector addition, vector multiplication, and scalar addition.

405 It is shown in [ADIW24]) that:

- 406 (1) For a definable $f : L \rightarrow \mathcal{L}$, the approximating operators φ may be taken to
 407 be *polynomials* of the input features, and
 408 (2) Definable transforms $f : L \rightarrow \mathcal{L}$ are precisely those that extend to contin-
 409 uous $\tilde{f} : \mathcal{L} \rightarrow \mathcal{L}$ (this is the property of *extendibility* mentioned above).

410 This motivates the following definition.

411 **Definition 2.4.** We say that a CCS (L, \mathcal{P}, Γ) satisfies the *Extendability Axiom* if
 412 for all $\gamma \in \Gamma$, there is $\tilde{\gamma} : \mathcal{L}_{\text{sh}} \rightarrow \mathcal{L}_{\text{sh}}$ such that for every sizer r_\bullet there is a sizer s_\bullet
 413 such that $\tilde{\gamma}|_{\mathcal{L}[r_\bullet]} : \mathcal{L}[r_\bullet] \rightarrow \mathcal{L}[s_\bullet]$ is continuous. We refer to $\tilde{\gamma}$ as a *free* extension
 414 of γ .

415 By the preceding remarks, the Extendability Axiom says that the elements of
 416 the semigroup Γ are definable. For the rest of the paper, fix for each $\gamma \in \Gamma$ a free
 417 extension $\tilde{\gamma}$ of γ . For any $\Delta \subseteq \Gamma$, let $\tilde{\Delta}$ denote $\{\tilde{\gamma} : \gamma \in \Delta\}$.

418 For a detailed discussion of the Extendability Axiom, we refer the reader to [ADIW24].

419 For an illustrative example, we can frame Newton’s polynomial root approxima-
 420 tion method in the context of a CCS (see Example 5.6 of [ADIW24] for details) as
 421 follows. Begin by considering the extended complex numbers $\hat{\mathbb{C}} := \mathbb{C} \cup \{\infty\}$ with
 422 the usual Riemann sphere topology that makes it into a compact space (where
 423 unbounded sequences converge to ∞). In fact, not only is this space compact
 424 but it is covered by the shard given by the sizer $(1, 1, 1)$ (the unit sphere is con-
 425 tained in the cube $[-1, 1]^3$). The space $\hat{\mathbb{C}}$ is homeomorphic to the usual unit sphere
 426 $S^2 := \{(x, y, z) : x^2 + y^2 + z^2 = 1\}$ of \mathbb{R}^3 , by means of the stereographic pro-
 427 jection and its inverse $\hat{\mathbb{C}} \rightarrow S^2$. This function is regarded as a triple of predi-
 428 cates $x, y, z : \hat{\mathbb{C}} \rightarrow [-1, 1]$ where each will map an extended complex number to

its corresponding real coordinate on the cube $[-1, 1]^3$. Now fix the cubic complex polynomial $p(s) := s^3 - 1$, and consider the map which performs one step in Newton's method at a particular (extended) complex number s , for finding a root of p , $\gamma_p : \hat{\mathbb{C}} \rightarrow \hat{\mathbb{C}}$. The explicit inner workings of γ_p are irrelevant for this example, except for the fact that it is a continuous mapping. It follows that $(S^2, \{x, y, z\}, \{\gamma_p^k : k \in \mathbb{N}\})$ is a CCS. The idea is that repeated applications of $\gamma_p(s), \gamma_p \circ \gamma_p(s), \gamma_p \circ \gamma_p \circ \gamma_p(s), \dots$ would approximate a root of p provided s was a good enough initial guess.

3. CLASSIFYING DEEP COMPUTATIONS

3.1. NIP, Rosenthal compacta, and deep computations. Under what conditions are deep computations Baire class 1, and thus well-behaved according to our framework, on type-shards? The following theorem says that, under the assumption that \mathcal{P} is countable, the space of deep computations is a Rosenthal compactum (when restricted to shards) if and only if the set of computations satisfies the NIP feature by feature. Hence, we can import the theory of Rosenthal compacta into this framework of deep computations.

Theorem 3.1. *Let (L, \mathcal{P}, Γ) be a compositional computational structure (Definition 2.3) satisfying the Extendability Axiom (Definition 2.4) with \mathcal{P} countable. Let R be an exhaustive collection of sizers. Let $\Delta \subseteq \Gamma$ be R -confined. The following are equivalent.*

- (1) $\overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}} \subseteq B_1(\mathcal{L}[r_\bullet], \mathcal{L}[r_\bullet])$ for all $r_\bullet \in R$.
- (2) $\pi_P \circ \tilde{\Delta}|_{\mathcal{L}[r_\bullet]}$ satisfies the NIP for all $P \in \mathcal{P}$ and $r_\bullet \in R$; that is, for all $P \in \mathcal{P}$, $r_\bullet \in R$, $a < b$, $\{\gamma_n\}_{n \in \mathbb{N}} \subseteq \Delta$ there are finite disjoint $E, F \subseteq \mathbb{N}$ such that

$$L[r_\bullet] \cap \bigcap_{n \in E} (\pi_P \circ \gamma_n)^{-1}(-\infty, a] \cap \bigcap_{n \in F} (\pi_P \circ \gamma_n)^{-1}[b, \infty) = \emptyset.$$

Moreover, if any (hence all) of the preceding conditions hold, then every deep computation $f \in \overline{\Delta}$ can be extended to a Baire-1 function on shards, i.e., there is $\tilde{f} : \mathcal{L}_{sh} \rightarrow \mathcal{L}_{sh}$ such that $\tilde{f}|_{\mathcal{L}[r_\bullet]} \in B_1(\mathcal{L}[r_\bullet], \mathcal{L}[r_\bullet])$ for all $r_\bullet \in R$. In particular, on each shard every deep computation is the pointwise limit of a countable sequence of computations.

Proof. Since \mathcal{P} is countable, $\mathcal{L}[r_\bullet] \subseteq \mathbb{R}^\mathcal{P}$ is Polish. Also, the Extendability Axiom implies that $\pi_P \circ \tilde{\Delta}|_{\mathcal{L}[r_\bullet]}$ is a pointwise bounded set of continuous functions for all $P \in \mathcal{P}$. Hence, Theorem 1.12 and Lemma 1.13 prove the equivalence of (1) and (2). If (1) holds and $f \in \overline{\Delta}$, then write $f = \text{Ulim}_i \gamma_i$ as an ultralimit. Define $\tilde{f} := \text{Ulim}_i \tilde{\gamma}_i$. Hence, for all $r_\bullet \in R$ we have $\tilde{f}|_{\mathcal{L}[r_\bullet]} \in \overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}} \subseteq B_1(\mathcal{L}[r_\bullet], \mathcal{L}[r_\bullet])$. That every deep computation is a pointwise limit of a countable sequence of computations follows from the fact that for a Polish space X every compact subset of $B_1(X)$ is Fréchet-Urysohn (that is, a space where topological closures coincide with sequential closures, see Theorem 3F in [BFT78] or Theorem 4.1 in [Deb13]). \square

3.2. The Todorčević trichotomy and levels of PAC learnability. Given a countable set Δ of computations satisfying the NIP on features and shards (condition (2) of Theorem 3.1) we have that $\overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}}$ (for a fixed sizer r_\bullet) is a separable

467 *Rosenthal compactum* (see Definition 1.9). Todorčević proved a remarkable tri-
468 chotomy for Rosenthal compacta [Tod99], and later Argyros, Dodos, Kanellopou-
469 los [ADK08] proved an heptachotomy that refined Todorčević’s classification. In
470 this section, inspired by the work of Glasner and Megrelishvili [GM22], we study
471 ways in which this classification allows us obtain different levels of PAC-learnability
472 and NIP.

473 Recall that a topological space X is *hereditarily separable* (HS) if every subspace
474 is separable and that X is *first countable* if every point in X has a countable
475 local basis. Every separable metrizable space is hereditarily separable, and R. Pol
476 proved that every hereditarily separable Rosenthal compactum is first countable
477 (see section 10 of [Deb13]). This suggests the following definition:

478 **Definition 3.2.** Let (L, \mathcal{P}, Γ) be a CCS satisfying the Extendability Axiom and R
479 be an exhaustive collection of sizers. Let $\Delta \subseteq \Gamma$ be an R -confined countable set of
480 computations satisfying the NIP on shards and features (condition (2) in Theorem
481 3.1). We say that Δ is:

- 482 (i) NIP_1 if $\overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}}$ is first countable for every $r_\bullet \in R$.
- 483 (ii) NIP_2 if $\overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}}$ is hereditarily separable for every $r_\bullet \in R$.
- 484 (iii) NIP_3 if $\overline{\tilde{\Delta}|_{\mathcal{L}[r_\bullet]}}$ is metrizable for every $r_\bullet \in R$.

485 Observe that $\text{NIP}_3 \Rightarrow \text{NIP}_2 \Rightarrow \text{NIP}_1 \Rightarrow \text{NIP}$. A natural question that would con-
486 tinue this work is to find examples of CCS that separate these levels of NIP. In
487 [Tod99], Todorčević isolates three canonical examples of Rosenthal compacta that
488 witness the failure of the converse implications above.

489 We now present some separable and non-separable examples of Rosenthal com-
490 pacta:

491 Examples 3.3.

- 492 (1) *Alexandroff compactification of a discrete space of size continuum.* For
493 each $a \in 2^{\mathbb{N}}$ consider the map $\delta_a : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ given by $\delta_a(x) = 1$ if $x = a$ and
494 $\delta_a(x) = 0$ otherwise. Let $A(2^{\mathbb{N}}) = \{\delta_a : a \in 2^{\mathbb{N}}\} \cup \{0\}$, where 0 is the zero
495 map. Notice that $A(2^{\mathbb{N}})$ is a compact subset of $B_1(2^{\mathbb{N}})$, in fact $\{\delta_a : a \in 2^{\mathbb{N}}\}$
496 is a discrete subspace of $B_1(2^{\mathbb{N}})$ and its pointwise closure is precisely $A(2^{\mathbb{N}})$.
497 Hence, this is a Rosenthal compactum which is not first countable. Notice
498 that this space is also not separable.
- 499 (2) *Extended Alexandroff compactification.* For each finite binary sequence $s \in$
500 $2^{<\mathbb{N}}$, let $v_s : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ be given by $v_s(x) = 1$ if x extends s and $v_s(x) = 0$
501 otherwise. Let $\hat{A}(2^{\mathbb{N}})$ be the pointwise closure of $\{v_s : s \in 2^{<\mathbb{N}}\}$, i.e.,
502 $\hat{A}(2^{\mathbb{N}}) = A(2^{\mathbb{N}}) \cup \{v_s : s \in 2^{<\mathbb{N}}\}$. Note that this space is a separable
503 Rosenthal compactum which is not first countable.
- 504 (3) *Split Cantor.* Let $<$ be the lexicographic order in the space of infinite
505 binary sequences, i.e., $2^{\mathbb{N}}$. For each $a \in 2^{\mathbb{N}}$ let $f_a^- : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ be given by
506 $f_a^-(x) = 1$ if $x < a$ and $f_a^-(x) = 0$ otherwise. Let $f_a^+ : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ be given
507 by $f_a^+(x) = 1$ if $x \leq a$ and $f_a^+(x) = 0$ otherwise. The split Cantor is the
508 space $S(2^{\mathbb{N}}) = \{f_a^- : a \in 2^{\mathbb{N}}\} \cup \{f_a^+ : a \in 2^{\mathbb{N}}\}$. This is a separable Rosenthal
509 compactum. One example of a countable dense subset is the set of all f_a^+
510 and f_a^- where a is an infinite binary sequence that is eventually constant.
511 Moreover, it is hereditarily separable but it is not metrizable.

- (4) *Alexandroff Duplicate.* Let K be any compact metric space and consider the Polish space $X = C(K) \sqcup K$, i.e., the disjoint union of $C(K)$ (with its supremum norm topology) and K . For each $a \in K$ define $g_a^0, g_a^1 : X \rightarrow \mathbb{R}$ as follows:

$$g_a^0(x) = \begin{cases} x(a), & x \in C(K) \\ 0, & x \in K \end{cases}$$

$$g_a^1(x) = \begin{cases} x(a), & x \in C(K) \\ \delta_a(x), & x \in K \end{cases}$$

Let $D(K) = \{g_a^0 : a \in K\} \cup \{g_a^1 : a \in K\}$. Notice that $D(K)$ is a first countable Rosenthal compactum. It is not separable if K is uncountable. The interesting case will be when $K = 2^{\mathbb{N}}$.

- (5) *Extended Alexandroff Duplicate of the split Cantor.* For each finite binary sequence $t \in 2^{<\mathbb{N}}$ let $a_t \in 2^{\mathbb{N}}$ be the sequence starting with t and ending with 0's and let $b_t \in 2^{\mathbb{N}}$ be the sequence starting with t and ending with 1's. Define $h_t : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ by

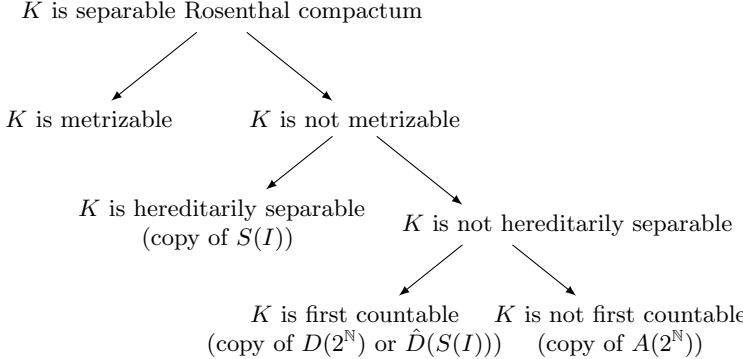

$$h_t(x) = \begin{cases} 0, & x < a_t \\ 1/2, & a_t \leq x \leq b_t \\ 1, & b_t < x \end{cases}$$

Let $\hat{D}(S(2^{\mathbb{N}}))$ be the pointwise closure of the set $\{h_t : t \in 2^{<\mathbb{N}}\}$. Hence, $\hat{D}(S(2^{\mathbb{N}}))$ is a separable first countable Rosenthal compactum which is not hereditarily separable. In fact, it contains an uncountable discrete subspace (see Theorem 5 in [Tod99]).

Theorem 3.4 (Todorčević's Trichotomy, [Tod99], Theorem 3 in [ADK08]). *Let K be a separable Rosenthal Compactum.*

- (i) *If K is hereditarily separable but non-metrizable, then $S(2^{\mathbb{N}})$ embeds into K .*
- (ii) *If K is first countable but not hereditarily separable, then either $D(2^{\mathbb{N}})$ or $\hat{D}(S(2^{\mathbb{N}}))$ embeds into K .*
- (iii) *If K is not first countable, then $A(2^{\mathbb{N}})$ embeds into K .*

We thus have the following classification:

The definitions provided here for NIP_i ($i = 1, 2, 3$) are topological. This raises the following question:

Question 3.5. Is there a non-topological characterization for NIP_i , $i = 1, 2, 3$?

530 **3.3. The Argyros-Dodos-Kanellopoulos heptachotomy, and approxima-**
 531 **bility of deep computation by minimal classes.** In the three separable three
 532 cases given in 3.3, namely, $(\hat{A}(2^{\mathbb{N}}), S(2^{\mathbb{N}}) \text{ and } \hat{D}(S(2^{\mathbb{N}})))$, the countable dense sub-
 533 sets are indexed by the binary tree $2^{<\mathbb{N}}$. This choice of index is useful for two
 534 reasons:

- 535 (1) Our emphasis is computational. Elements of $2^{<\mathbb{N}}$ represent finite bitstrings,
 536 i.e., standard computations, while Rosenthal compacta represent deep com-
 537 putations, i.e., limits of finite computations. Mathematically, deep computa-
 538 tions are pointwise limits of standard computations. However, computa-
 539 tionally, we are interested in the manner (and the efficiency) in which the
 540 approximations can occur.
- 541 (2) The Ramsey theory of perfect subsets of the Cantor space $2^{\mathbb{N}}$ can be im-
 542 ported to analyze the behavior of the accumulation points. Since $2^{<\mathbb{N}}$ is
 543 countable, we can always choose this index for the countable dense subsets.
 544 This is done in [ADK08].

545 **Definition 3.6.** Let X be a Polish space.

- 546 (1) If I is a countable and $\{f_i : i \in I\} \subseteq \mathbb{R}^X$, $\{g_i : i \in I\} \subseteq \mathbb{R}^X$ are two
 547 pointwise families by I , we say that $\{f_i : i \in I\}$ and $\{g_i : i \in I\}$ are
 548 *equivalent* if and only if the map $f_i \mapsto g_i$ is extended to a homeomorphism
 549 from $\overline{\{f_i : i \in I\}}$ to $\overline{\{g_i : i \in I\}}$.
- 550 (2) If $\{f_t : t \in 2^{<\mathbb{N}}\}$ is a pointwise bounded family, we say that $\{f_t : t \in 2^{<\mathbb{N}}\}$
 551 is *minimal* if and only if for every dyadic subtree $\{s_t : t \in 2^{<\mathbb{N}}\}$ of $2^{<\mathbb{N}}$,
 552 $\{f_{s_t} : t \in 2^{<\mathbb{N}}\}$ is equivalent to $\{f_t : t \in 2^{<\mathbb{N}}\}$.

553 One of the main results in [ADK08] is that, up to equivalence, there are seven
 554 minimal families of Rosenthal compacta and that for every relatively compact $\{f_t :$
 555 $t \in 2^{<\mathbb{N}}\} \subseteq B_1(X)$ there is a dyadic subtree $\{s_t : t \in 2^{<\mathbb{N}}\}$ such that $\{f_{s_t} : t \in 2^{<\mathbb{N}}\}$
 556 is equivalent to one of the minimal families. We shall describe the seven minimal
 557 families next. We follow the same notation as in [ADK08]. For any node $t \in 2^{<\mathbb{N}}$,
 558 let us denote by $t^\frown 0^\infty$ ($t^\frown 1^\infty$) the infinite binary sequence starting with t and
 559 continuing will all 0's (respectively, all 1's). Fix a regular dyadic subtree $R = \{s_t :$
 560 $t \in 2^{<\mathbb{N}}\}$ of $2^{<\mathbb{N}}$ (i.e., a dyadic subtree such that every level of R is contained
 561 in a level of $2^{<\mathbb{N}}$) with the property that for all $s, s' \in R$, $s^\frown 0^\infty \neq s'^\frown 0^\infty$ and
 562 $s^\frown 1^\infty \neq s'^\frown 1^\infty$. Given $t \in 2^{<\mathbb{N}}$, let v_t be the characteristic function of the set
 563 $\{x \in 2^{\mathbb{N}} : x \text{ extends } t\}$. Let $<$ be the lexicographic order in $2^{\mathbb{N}}$. Given $a \in 2^{\mathbb{N}}$,
 564 let $f_a^+ : 2^{\mathbb{N}} \rightarrow \{0, 1\}$ be the characteristic function of $\{x \in 2^{\mathbb{N}} : a \leq x\}$ and let
 565 $f_a^- : 2^{\mathbb{N}} \rightarrow \{0, 1\}$ be the characteristic function of $\{x \in 2^{\mathbb{N}} : a < x\}$. Given two
 566 maps $f, g : 2^{\mathbb{N}} \rightarrow \mathbb{R}$ we denote by $(f, g) : 2^{\mathbb{N}} \sqcup 2^{\mathbb{N}} \rightarrow \mathbb{R}$ the function which is f on
 567 the first copy of $2^{\mathbb{N}}$ and g on the second copy of $2^{\mathbb{N}}$.

- 568 (1) $D_1 = \{\frac{1}{|t|+1} v_t : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_1} = A(2^{\mathbb{N}})$.
- 569 (2) $D_2 = \{s_t^\frown 0^\infty : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_2} = 2^{\leq N}$.
- 570 (3) $D_3 = \{f_{s_t^\frown 0^\infty}^+ : t \in 2^{<\mathbb{N}}\}$. This is a discrete in $\overline{D_3} = S(2^{\mathbb{N}})$.
- 571 (4) $D_4 = \{f_{s_t^\frown 1^\infty}^- : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_4} = S(2^{\mathbb{N}})$.
- 572 (5) $D_5 = \{v_t : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_5} = \hat{A}(2^{\mathbb{N}})$.
- 573 (6) $D_6 = \{(v_{s_t}, s_t^\frown 0^\infty) : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_6} = \hat{D}(2^{\mathbb{N}})$.
- 574 (7) $D_7 = \{(v_{s_t}, x_{s_t^\frown 0^\infty}^+) : t \in 2^{<\mathbb{N}}\}$. This is discrete in $\overline{D_7} = \hat{D}(S(2^{\mathbb{N}}))$

575 **Theorem 3.7** (Heptacotomy of minimal families, Theorem 2 in [ADK08]). *Let*
 576 *X* *be Polish. For every relatively compact* $\{f_t : t \in 2^{<\mathbb{N}}\} \subseteq B_1(X)$, *there exists*
 577 *i* = 1, 2, ..., 7 *and a regular dyadic subtree* $\{s_t : t \in 2^{<\mathbb{N}}\}$ *of* $2^{<\mathbb{N}}$ *such that* $\{f_{s_t} :$
 578 $t \in 2^{<\mathbb{N}}\}$ *is equivalent to* D_i . *Moreover, all* D_i *are minimal and mutually non-*
 579 *equivalent.*

580 4. MEASURE-THEORETIC VERSIONS OF NIP AND ESSENTIAL COMPUTABILITY OF
 581 DEEP COMPUTATIONS

582 We now turn to the question: what happens when \mathcal{P} is uncountable? Notice
 583 that the countability assumption is crucial in the proof of Theorem 1.12 essentially
 584 because it makes $\mathbb{R}^{\mathcal{P}}$ a Polish space. For the uncountable case, we may lose Baire-1
 585 definability so we shall replace $B_1(X)$ by a larger class.

586 5. A MEASURE-THEORETIC VERSIONS OF NIP

587 Recall that the *raison d'être* of the class of Baire-1 functions is to have a class
 588 that contains the continuous functions but is closed under pointwise limits, and
 589 that (Fact 1.2) for perfectly normal X , a function f is in $B_1(X, Y)$ if and only if
 590 $f^{-1}[U]$ is an F_σ subset of X for every open $U \subseteq Y$. This motivates the following
 591 definition:

592 **Definition 5.1.** Given a Hausdorff space X and a measurable space (Y, Σ) , we say
 593 that $f : X \rightarrow Y$ is *universally measurable* (with respect to Σ) if $f^{-1}(E)$ is Borel
 594 for every $E \in \Sigma$, i.e., $f^{-1}(E)$ is μ -measurable for every Radon probability measure
 595 μ on X . When $Y = \mathbb{R}$ we will always take $\Sigma = \mathcal{B}(\mathbb{R})$, the Borel σ -algebra of \mathbb{R} .
 596 In this case, a function $f : X \rightarrow \mathbb{R}$ is universally measurable if and only if $f^{-1}(U)$
 597 is μ -measurable for every Radon probability measure μ on X and every open set
 598 $U \subseteq \mathbb{R}$.

599 Intuitively, a function is universally measurable if it is “measurable no matter
 600 which reasonable way you try to measure things on its domain”. The concept
 601 of universal measurability emerged from work of Kallianpur and Sazonov, in the
 602 late 1950's and 1960s, , with later developments by Blackwell, Darst, and others,
 603 building on earlier ideas of Gnedenko and Kolmogorov from the 1950s. See [Pap02,
 604 Chapters 1 and 2].

605 **Notation 5.2.** Following [BFT78], the collection of all universally measurable real-
 606 valued functions will be denoted by $M_r(X)$.

607 In the context of deep computations, we will be interested in transition maps
 608 from a state space $L \subseteq \mathbb{R}^{\mathcal{P}}$ to itself. There are two natural σ -algebras one can
 609 consider in the product space $\mathbb{R}^{\mathcal{P}}$: the Borel σ -algebra, i.e., the σ -algebra generated
 610 by open sets in $\mathbb{R}^{\mathcal{P}}$, and the cylinder σ -algebra, i.e., the σ -algebra generated by the
 611 sub-basic open sets in $\mathbb{R}^{\mathcal{P}}$. Note that when \mathcal{P} is countable, both σ -algebras coincide
 612 but in general the cylinder σ -algebra is strictly smaller. We will use the cylinder
 613 σ -algebra to define universally measurable maps $f : \mathbb{R}^{\mathcal{P}} \rightarrow \mathbb{R}^{\mathcal{P}}$. The reason for this
 614 choice is the following characterization:

615 **Lemma 5.3.** *Let X be a Hausdorff space and $Y = \prod_{i \in I} Y_i$ be any product of*
 616 *measurable spaces (Y_i, Σ_i) for $i \in I$. Let Σ_Y be the cylinder σ -algebra generated by*
 617 *the measurable spaces (Y_i, Σ_i) . Let $f : X \rightarrow Y$. The following are equivalent:*

- 618 (i) *$f : X \rightarrow Y$ is universally measurable (with respect to Σ_Y).*

619 (ii) $\pi_i \circ f : X \rightarrow Y_i$ is universally measurable (with respect to Σ_i) for all $i \in I$.

620 *Proof.* (i) \Rightarrow (ii) is clear since the projection maps π_i are measurable and the composition of measurable functions is measurable. To prove (ii) \Rightarrow (i), suppose that 621 $C = \prod_{i \in I} C_i$ is a measurable cylinder and let J be the finite set of $i \in I$ such that 622 $C_i \neq Y_i$. Then, $C = \bigcap_{i \in J} \pi_i^{-1}(C_i)$, so $f^{-1}(C) = \bigcap_{i \in J} (\pi_i \circ f)^{-1}(C_i)$ is a universally 623 measurable set by assumption. \square

625 The preceding lemma says that a transition map is universally measurable if and 626 only if it is universally measurable on all its features. In other words, we can check 627 measurability of a transition just by checking measurability feature by feature. We 628 will denote by $M_r(X, \mathbb{R}^P)$ the collection of all universally measurable functions 629 $f : X \rightarrow \mathbb{R}^P$ (with respect to the cylinder σ -algebra), endowed with the topology 630 of pointwise convergence.

631 We will need the following result about NIP and universally measurable functions:

633 **Theorem 5.4** (Bourgain-Fremlin-Talagrand, Theorem 2F in [BFT78]). *Let X be a 634 Hausdorff space and $A \subseteq C(X)$ be pointwise bounded. The following are equivalent:*

- 635 (i) $\overline{A} \subseteq M_r(X)$.
- 636 (ii) *For every compact $K \subseteq X$, $A|_K$ satisfies the NIP.*
- 637 (iii) *For every Radon measure μ on X , A is relatively countably compact in 638 $\mathcal{M}^0(X, \mu)$, i.e., every countable subset of A has an accumulation point in 639 $\mathcal{M}^0(X, \mu)$.*

640 **5.1. Essential computability of deep computations.** We now wish to define 641 the concept of a deep computation being computable except a set of arbitrarily 642 small measure “no matter which reasonable way you try to measure things on its 643 domain” (see the remarks following definition). This is the concept of *universal 644 measurability* defined below (Definition). To motivate the definition, we need to 645 recall two facts:

- 646 (1) Littlewood’s second principle states that every Lebesgue measurable function 647 is “nearly continuous”. The formal version of this, which is Luzin’s 648 theorem, states that if (X, Σ, μ) a Radon measure space and Y be a second- 649 countable topological space (e.g., $Y = \mathbb{R}^P$ with P countable) equipped with 650 a Borel algebra, then any given $f : X \rightarrow Y$ is measurable if and only if for 651 every $E \in \Sigma$ and every $\varepsilon > 0$ there exists a closed $F \subseteq E$ such that the 652 restriction $f|F$ is continuous.
- 653 (2) Computability of deep computations can is characterized in terms of con- 654 tinuous extendibility of computations. This is at the core of [ADIW24].

655 These facts motivate the following definition:

656 **Definition 5.5.** Let (L, \mathcal{P}, Γ) be a CCS. We say that a transition $f : L \rightarrow L$ 657 is *universally essentially computable* if and only if there exists $\tilde{f} : \mathcal{L}_{sh} \rightarrow \mathcal{L}_{sh}$ 658 extending f such that for every sizer r_\bullet there is a sizer s_\bullet such that the restriction 659 $\tilde{f}|_{\mathcal{L}[r_\bullet]} : \mathcal{L}[r_\bullet] \rightarrow \mathcal{L}[s_\bullet]$ is universally measurable, i.e., $\pi_P \circ \tilde{f}|_{\mathcal{L}[r_\bullet]} : \mathcal{L}[r_\bullet] \rightarrow [-s_P, s_P]$ 660 is μ -measurable for every Radon probability measure μ on $\mathcal{L}[r_\bullet]$.

661 **5.2. Bourgain-Fremlin-Talagrand, NIP, and essential computability of 662 deep computations.** Theorem 5.4 immediately yields the following.

663 **Theorem 5.6.** Let (L, \mathcal{P}, Γ) be a CCS satisfying the Extendability Axiom. Let R be
 664 an exhaustive collection of sizers. Let $\Delta \subseteq \Gamma$ be R -confined. If $\pi_P \circ \Delta|_{L[r_\bullet]}$ satisfies
 665 the NIP for all $P \in \mathcal{P}$ and all $r_\bullet \in R$, then every deep computation is universally
 666 essentially computable.

667 *Proof.* By the Extendability Axiom, Theorem 5.4 and lemma 1.13 we have that
 668 $\pi_P \circ \tilde{\Delta}|_{\mathcal{L}[r_\bullet]} \subseteq M_r(\mathcal{L}[r_\bullet])$ for all $r_\bullet \in R$ and $P \in \mathcal{P}$. Let $f \in \overline{\Delta}$ be a deep
 669 computation. Write $f = \mathcal{U} \lim_i \gamma_i$ as an ultralimit of computations in Δ . Define
 670 $\tilde{f} := \mathcal{U} \lim_i \tilde{\gamma}_i$. Then, for all $r_\bullet \in R$ and $P \in \mathcal{P}$ $\pi_P \circ \tilde{\gamma}_i|_{\mathcal{L}[r_\bullet]} \in M_r(\mathcal{L}[r_\bullet])$ for all
 671 i , so $\pi_P \circ f|_{\mathcal{L}[r_\bullet]} \in \pi_P \circ \tilde{\Delta}|_{\mathcal{L}[r_\bullet]} \subseteq M_r(\mathcal{L}[r_\bullet])$. \square

672 **Question 5.7.** Under the same assumptions of the preceding theorem, suppose
 673 that every deep computation of Δ is universally essentially computable. Must
 674 $\pi_P \circ \Delta|_{L[r_\bullet]}$ have the NIP for all $P \in \mathcal{P}$ and all $r_\bullet \in R$?

675 **5.3. Talagrand stability, Fremlin's dichotomy, NIP, and essential com-
 676 putability of deep computations.** There is another notion closely related to
 677 NIP, introduced by Talagrand in [Tal84] while studying Pettis integration. Suppose
 678 that X is a compact Hausdorff space and $A \subseteq \mathbb{R}^X$. Let μ be a Radon probability
 679 measure on X . Given a μ -measurable set $E \subseteq X$, a positive integer k and real
 680 numbers $a < b$. we write:

$$D_k(A, E, a, b) = \bigcup_{f \in A} \{x \in E^{2k} : f(x_{2i}) \leq a, f(x_{2i+1}) \geq b \text{ for all } i < k\}$$

681 We say that A is *Talagrand μ -stable* if and only if for every μ -measurable set
 682 $E \subseteq X$ of positive measure and for every $a < b$ there is $k \geq 1$ such that

$$(\mu^{2k})^*(D_k(A, E, a, b)) < (\mu(E))^{2k},$$

683 where μ^* denotes the outer measure (we work with outer since the sets $D_k(A, E, a, b)$
 684 need not be μ -measurable). This is certainly the case when A is a countable set of
 685 continuous (or μ -measurable) functions.

686 **Notation 5.8.** For a measure μ on a set X , the set of all μ -measurable functions
 687 will denoted by $\mathcal{M}^0(X, \mu)$.

688 The following lemma establishes that Talagrand stability is a way to ensure that
 689 deep computations are definable by measurable functions. We include a proof for
 690 the reader's convenience.

691 **Lemma 5.9.** If A is Talagrand μ -stable, then \overline{A} is also Talagrand μ -stable and
 692 $\overline{A} \subseteq \mathcal{M}^0(X, \mu)$.

693 *Proof.* First, observe that a subset of a μ -stable set is μ -stable. To show that \overline{A} is
 694 μ -stable, observe that $D_k(\overline{A}, E, a, b) \subseteq D_k(A, E, a', b')$ where $a < a' < b' < b$ and E
 695 is a μ -measurable set with positive measure. It suffices to show that $\overline{A} \subseteq \mathcal{M}^0(X, \mu)$.
 696 Suppose that there exists $f \in \overline{A}$ such that $f \notin \mathcal{M}^0(X, \mu)$. By a characterization
 697 of measurable functions (see 413G in [Fre03]), there exists a μ -measurable set E
 698 of positive measure and $a < b$ such that $\mu^*(P) = \mu^*(Q) = \mu(E)$ where $P = \{x \in E : f(x) \leq a\}$ and $Q = \{x \in E : f(x) \geq b\}$. Then, for any $k \geq 1$: $(P \times Q)^k \subseteq D_k(\{f\}, E, a, b)$ so $(\mu^{2k})^*(D_k(\{f\}, E, a, b)) = (\mu^*(P)\mu^*(Q))^k = (\mu(E))^{2k}$. Thus,
 700 $\{f\}$ is not μ -stable, but we argued before that a subset of a μ -stable set must be
 701 μ -stable. \square

703 We say that A is *universally Talagrand stable* if A is Talagrand μ -stable for every
 704 Radon probability measure μ on X . An argument similar to the proof of 5.4, yields
 705 the following:

706 **Theorem 5.10.** *Let (L, \mathcal{P}, Γ) be a CCS satisfying the Extendability Axiom. If
 707 $\pi_P \circ \Delta|_{L[r_\bullet]}$ is universally Talagrand stable for all $P \in \mathcal{P}$ and all sizers r_\bullet , then
 708 every deep computation is universally essentially computable.*

709 It is then natural to ask: what is the relationship between Talagrand stability
 710 and the NIP? The following dichotomy will be useful.

711 **Lemma 5.11** (Fremlin's Dichotomy, 463K in [Fre03]). *If (X, Σ, μ) is a perfect
 712 σ -finite measure space (in particular, for X compact and μ a Radon probability
 713 measure on X) and $\{f_n : n \in \mathbb{N}\}$ be a sequence of real-valued measurable functions
 714 on X , then either*

- 715 (i) $\{f_n : n \in \mathbb{N}\}$ has a subsequence that converges μ -almost everywhere, or
- 716 (ii) $\{f_n : n \in \mathbb{N}\}$ has a subsequence with no μ -measurable accumulation point
 717 in \mathbb{R}^X .

718 The preceding lemma can be considered as a measure-theoretic version of Rosen-
 719 thal's Dichotomy. Combining this dichotomy with the Theorem 5.4 we get the
 720 following result:

721 **Theorem 5.12.** *Let X be a Hausdorff space and $A \subseteq C(X)$ be pointwise bounded.
 722 The following are equivalent:*

- 723 (i) $\overline{A} \subseteq M_r(X)$.
- 724 (ii) For every compact $K \subseteq X$, $A|_K$ satisfies the NIP.
- 725 (iii) For every Radon measure μ on X , A is relatively countably compact in
 726 $\mathcal{M}^0(X, \mu)$, i.e., every countable subset of A has an accumulation point in
 727 $\mathcal{M}^0(X, \mu)$.
- 728 (iv) For every Radon measure μ on X and every sequence $\{f_n : n \in \mathbb{N}\} \subseteq A$,
 729 there is a subsequence that converges μ -almost everywhere.

730 *Proof.* Notice that the equivalence (i)-(iii) is Theorem 5.4. Notice that the equivalence of (iii) and (iv) is Fremlin's Dichotomy (Theorem 5.11). \square

732 Finally, it is natural to ask what the connection is between Talagrand stability
 733 and NIP.

734 **Proposition 5.13.** *Let X be a compact Hausdorff space and $A \subseteq C(X)$ be point-
 735 wise bounded. If A is universally Talagrand stable, then A satisfies the NIP.*

736 *Proof.* By Theorem 5.4, it suffices to show that A is relatively countably compact in
 737 $\mathcal{M}^0(X, \mu)$ for all Radon probability measure μ on X . Since A is Talagrand μ -stable
 738 for any such μ , we have $\overline{A} \subseteq \mathcal{M}^0(X, \mu)$. In particular, A is relatively countably
 739 compact in $\mathcal{M}^0(X, \mu)$. \square

740 **Question 5.14.** Is the converse true?

741 The following two results suggest that the precise connection between Talagrand
 742 stability and NIP may be sensitive to set-theoretic axioms (even assuming count-
 743 ability of A).

744 **Theorem 5.15** (Talagrand, Theorem 9-3-1(a) in [Tal84]). *Let X be a compact
745 Hausdorff space and $A \subseteq M_r(X)$ be countable and pointwise bounded. Assume that
746 $[0, 1]$ is not the union of $< \mathfrak{c}$ closed measure zero sets. If A satisfies the NIP, then
747 A is universally Talagrand stable.*

748 **Theorem 5.16** (Fremlin, Shelah, [FS93]). *It is consistent that there exists a countable
749 pointwise bounded set of Lebesgue measurable functions with the NIP which is
750 not Talagrand stable with respect to Lebesgue measure.*
